# DVILASER/PS Extensions to LaTEX 

Doug Maus<br>Bruce Baker<br>Textset, Incorporated

## Overview

The IATEX Document Preparation System is a collection of $\mathrm{T}_{⿷} \mathrm{X}$ macros designed to make it easy to produce high-quality documents. $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ was developed by Leslie Lamport - also the author of LATEX: A Document Preparation System which is published by Addison-Wesley Publishing Company. LATEX is in the public domain and is included in the standard $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ distribution available from Stanford University. It is also included in most proprietary implementations of $\mathrm{TEX}_{\mathrm{E}}$.

LATEX is based on the concept of a document as a set of structures (e.g. descriptions, tables, enumerated lists) called environments. Environments start with a \begin\{environment\} statement such } as \begin\{tabular\} or \begin\{verbatim\} and end } with an analogous \end\{environment\} statement. }

This article describes an upward compatible set of extensions to LATEX's picture environment implemented by Textset to take advantage of the graphics capabilities of PostScript language used by the Apple LaserWriter and other printers. Textset's $\mathrm{TEX}_{\mathrm{E}}$ output driver for the PostScript printers, DVILASER/PS, includes support which makes it easy to integrate user-supplied PostScript statements with the PostScript statements being generated automatically by DVILASER/PS as it converts TEX DVI files into PostScript format. The IATEX extensions are included free of charge with all DVILASER/PS distributions.

Copyright 1985, Textset, Inc. All rights reserved.
Editor's Note: this article was originally printed on an Apple LaserWriter using the Almost Computer Modern fonts, with the illustrations in Figure 1, Figure 3, Figure 4 and Figure 6 inserted by the DVILASER/PS program. For this special issue of TUGBOAT, it was reformatted, typeset on an Alphatype CRS using the new Computer Modern fonts, and the illustrations were reinserted manually.

The TEX macro package described here contains about 300 lines of code and has been dedicated to the public domain by Textset. Although the macros assume one is using Textset's DVILASER/PS program, they should be of general interest. The same strategy could be applied with other device drivers. In fact, similar extensions to $\mathrm{LAT}_{\mathrm{EX}}$ could be implemented for any printer with a reasonable graphics language.

Some of this work was funded by the University of Michigan and developed initially at the CAEN Apollo Lab, and many thanks are due to Leslie A. Olsen and our other friends at the College of Engineering.

## The LATEX Picture Environment

One of LATEX's nicest features is the picture environment. With it, one can "draw" pictures. The picture in Figure 1 was created by the $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ commands that are to the left of it.

The " $(1,1)(-150,27)$ " specifies how much space the picture should take up and also allows the user to move the picture around on the page. In the example, " $(1,1)$ " tells LATEX to allocate hardly any space at all for the picture - just an imaginary box 1 pt by 1 pt , though obviously the actual picture is much larger. The " $(-150,27)$ " positions the picture in the desired place by moving the whole picture to the right 150 pt and down 27 pt from where $\mathrm{LA} \mathrm{TEX}_{\mathrm{E}}$ would have otherwise have put it, at the next place a regular character would go that has dimensions 1 pt by 1 pt .

Within the LATEX picture environment, pictures normally are "drawn" by positioning special characters, in this case curved and straight line segments, in ways that give the appearance of circles and continuous lines. Circles are actually composed of four discrete curved segments, one for each quarter of the circle. LATEX carefully aligns them so that

## Figure 1.

Sample LATEX picture commands, and the resulting picture.

they print as a complete circle. Oblique lines, ones that are neither vertical nor horizontal, are composed of a number of shorter segments which are placed end on end and form what looks like a continuous line. These special characters are obtained from a set of special fonts (circle10, line10, lasy10, etc.) that are distributed with LATEX. Using these special fonts, LATEX "fools" TEX into drawing pictures even though TEX doesn't really have any graphics capabilities.

LATEX's picture environment is somewhat restrictive since "pictures" must be put together from the limited number of "pieces" available in the special LATEX fonts. LATEX carefully figures out the position of each circle or line segment. Longer lines, since they are made up of many shorter segments, cause longer execution and printing times. Even worse, creators of complex pictures often get the error "TEX capacity exceeded - sorry." This happens because $T_{E X}$ runs out of memory since there are too many "characters" on the page to handle. In addition, the user must be sure to use lines having only certain slopes, and be willing to accept circles of only certain diameters since in the standard IATEX distribution there are only 36 available slopes for straight lines and 10 different diameters for circles. Also, LATEX can only print hollow circles of diameters that are multiples of 4 pt in size. If a user selects an in-between size like 21pt, LATEX will pick the closest available size: 20 pt . The biggest hollow circle it can do is 40 pt - a little over half an inch - in diameter. The biggest solid circle is 15 pt in diameter. The steepest non-vertical slope available is $\pm \frac{5}{6}$. LATEX checks the slope arguments to make sure neither $\Delta x$

```
\begin{picture}(300,300)
    \put(150,200){\circle{70}} % head
    \put(140,205){\circle*{1}} % left eye
    \put(160,205){\circle*{1}} % right eye
    \put(150,193){\circle{10}} % mouth
    \put(150,165){\line(0,-1){85}} % body
    \put(150,150){\vector(-1,-6){15}} % left arm
    \put(150,150){\vector(2,-1){50}} % right arm
    \put(150,80){\line(-1,-1){50}} % left leg
    \put (150,80){\line(1,-7){15}} % right leg
\end{picture}
```

Figure 2.
This example exceeds standard IATEX's capabilities. Slopes specified for the left arm and right leg are too steep.
nor $\Delta y$ exceeds $\pm 6$, and that they are both integers. For vectors, because the arrowhead is drawn from a font too and slope availability in its case is even more limited, neither $\Delta x$ nor $\Delta y$ can exceed $\pm 4$.

Figure 2 demonstrates these problems by drawing the same picture with different slopes and diameters. No picture was produced when this was run under standard IATEX because first the " -6 " for the left arm exceeded $\pm 4$, caused a LATEX error message, and halted execution; then the " -7 " for the right leg exceeded $\pm 6$ and IATEX stopped again.

When these two simple problems were "corrected" by substituting " $(-1,-4)$ " for the left arm and " $(1,-6)$ " for the right leg, the picture still did not look as desired - the head was 40 pt in diameter instead of 70 pt . This messed up the body as well, causing the head to "hover" above the body. In

## Figure 3.

The left picture was produced by standard IATEX, the right picture by extended LATEX.

Figure 3, the left picture is how standard LATEX did it. On the right is the Extended IATEX version of the original example.

## The IATEX Picture Environment Extensions

 The PostScript printer language is very powerful. It has a very general and flexible set of capabilities enabling the creation of practically any textual or graphic image. It can draw letters, lines, and circles of virtually any size and slope. It can shade the inside of any closed figure it draws. And it allows lines of text to be drawn at any angle. The extended version of LATEX uses these PostScript capabilities to provide a number of features not normally possible with LATEX. All extensions are modelled closely after the way $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ normally does things.
## Extensions to Existing IATEX Commands

Line Thickness Standard LATEX provides two line thicknesses which are selected by typing either \thinlines or \thicklines inside the picture environment. These two declarations simply tell TEX which font to use, either line or linew, respectively. LATEX version 2.05 also provided a \linethickness\{\} command with which the user
could vary the thickness of non-oblique (vertical or horizontal) lines.

The latest release of $\mathrm{IATEX}_{\mathrm{E}}$ does not document the use of the \linethickness $\}$ command, probably because of the confusion which arose because it could only do non-oblique lines. With the IATEX extensions, though, it has been brought back. By typing something such as \linethickness\{5pt\} you can set the line thickness of a PostScript-drawn line or circle to 5 pt .
\thinlines is equivalent to the command \linethickness\{0.4pt\}. \thicklines is equivalent to typing \linethickness\{2pt\}. The Extended LATEX version of \thicklines draws a much thicker line than regular LATEX $\backslash$ thicklines does. Lines of intermediate thickness may be drawn with the \linethickness command.
Circles Circles of practically any diameter may be drawn. For hollow circles, use \circle\{diam\}. For solid circles, use \circle*\{diam\}.

Lines and Vectors Length and accuracy are virtually unlimited. Line lengths and \put coordinates need not be restricted to integer values as is the case normally with LATEX. However, whole numbers are still required for $\Delta x$ and $\Delta y$. This might seem restrictive, but if you want a line 34.5 points long with a slope of, say, 0.66 , try \line $(100,66)\{34.5\}$. A negative length causes the line to project opposite to the specified direction.

The \vector command uses the same syntax as the \line command and is just as versatile. The arrowhead points away from the location of the \put command. If you choose to use a thick line, you'll find the arrowhead may not look very good since it was designed to be used with thinner lines. In this case, use the \PSarrowhead command (described later) to custom-make your own vector with a bigger arrowhead.

## New LATEX Commands

PSoval If you've used IATEX's picture environment, you have seen that the loval command dcesn't really produce an oval at all; it's actually a rectangle with rounded corners. The corners are made up of the same fonts that make circles. Because \oval produces this unique-looking figure, the original IATEX macro was not redefined. Instead, a new command, \PSoval, was created. The syntax of \PSoval is as follows:
\PSoval \{width\}\{height\}
The \put command specifies the location of the center of the ellipse. Again, width and height are virtually unlimited.

You can get a solid oval by typing \PSoval* with the same syntax as \PSoval.

Two drawbacks - you can't use \PSoval to put text inside the oval. Use an extra \put command to do that if you need to. Also, this release of \PSoval has no provision for printing a portion of an oval something IATEX can do with \oval.
PSarrowhead Extended IATEX allows the user to control the shape of arrowheads. The user can make almost any size or shape of arrowhead desired. Add a line and get a custom-made vector as well. The syntax of the command is:
$\backslash$ PSarrowhead $(\Delta x, \Delta y)\{l e n g t h\}\{$ width\} $\{$ depth $\}$
where length, width and depth are defined in the summary. Keep $\Delta x$ and $\Delta y$ as whole numbers as in the \line and \vector commands. You can use almost any values you want for the length, width and depth. Use \PSarrowhead* with parameters as above to get a solid arrowhead.

The Extended IATEX ivector command uses a solid arrowhead that has a length of 8 pt , a width of 4 pt , and a depth of 2 pt .
PStilt Extended $I A T E X^{2}$, because it can use PostScript capabilities, allows the user to temporarily "rotate" the coordinate system of the page for individual lines. This means that text no longer has to be horizontal. In fact, it can be at any slope desired. The syntax of $\backslash$ PStilt is

## $\backslash$ PStilt $(\Delta x, \Delta y)\{o b j e c t$ or text $\}$

The user can put text or a picture object like a \framebox inside the third (brace enclosed) argument to $\backslash$ PStilt. This addition is very useful for labelling lines and rotating LATEX picture objects such as \oval's and \framebox'es.
PSpath Extended LATEX allows a much easier way of drawing straight lines - by naming the coordinates of the endpoints. In fact, a series of connected lines can be drawn with just one command. The syntax of \PSpath is

$$
\backslash \operatorname{PSpath}\left(x_{0}, y_{0}\right)\left\{\left(x_{1}, y_{1}\right)\left(x_{2}, y_{2}\right) \cdots\left(x_{n}, y_{n}\right)\right\}
$$

You don't even need the $\backslash$ put command, since the starting point is defined to be $\left(x_{0}, y_{0}\right)$ and the $n$ points are then connected in sequence. The number of points that can be connected using just one \PSpath varies from system to system. If you try to use a lot of points and get "capacity exceeded" errors, use more \PSpath commands.

The map example of Figure 6 demonstrates a series of points connected as one \PSpath.

## Conclusion

The IATEX extensions described in this article represent one way that TEX and PostScript can be used in a combination that is more powerful than either one alone. While the implementation described here is available only with Textset's DVILASER/PS program, other individuals or organizations might make use of a similar strategy to design their own individualized IATEX extensions.

## Note added in press

Leslie Lamport read a preprint of this article and had several much appreciated comments. He correctly guessed that we were not, at the time the article was written, aware of the new option that draws quadratic Bezier splines. He suggested for portability's sake that the extensions be enabled with a document-style option; the extensions in fact already must be enabled by a command and will work within any document style. We incorrectly stated that the \linethickness command was

## Figure 4.

Summary of Syntax of IATEX
Extensions.

Control Macros
$\backslash$ PSextensions0n
\PSextensionsOff Disables LATEX extensions and reverts to regular IATEX processing.

## Redefined Macros

\linethickness\{dimen\} Sets the thickness of all lines, including sloped lines, circles, and other geometric shapes. dimen is something such as $0.01 i n$ or 3 pt .
\thinlines Sets line thickness to 0.4 pt .
\thicklines Sets line thickness to 2pt.
\circle\{diam\} Puts a hollow circle at the current location with diameter diam, which can be to almost any size and accuracy desired.
\circle*\{diam\} Just like \circle, only the circle is solid.
$\backslash$ line $(\Delta x, \Delta y)\{l e n g t h\}$ Puts a line starting at the current point with a slope $\Delta y / \Delta x$ and a length defined as described in Lamport's book, where length is how far over the line is to go in terms of $x$-units, unless the line is vertical, where length then means the length of the line up or down. Use whole numbers for $\Delta x$ and $\Delta y$. length can be almost any number to virtually any accuracy.
\vector $(\Delta x, \Delta y)\{$ length \} Just like \line above, except in addition, a solid arrowhead is added at the other end of the line, pointing away from the $\backslash$ put point.

## New Macros

$\backslash$ PSarrowhead $(\Delta x, \Delta y)\{l e n g t h\}\{$ width $\}\{d e p t h\}$ Puts a hollow arrowhead with its tip at the position of the \put command, pointing at a slope $\Delta y / \Delta x$ and where the arguments are as shown:

When depth is positive, the figure produced is a concave arrowhead as shown. But when depth is negative, the figure is convex, and other shapes can then be created, like diamonds and rotated squares.
\PSarrowhead*\{same as above\} Puts a solid arrowhead at the position specified by the \put command.
$\backslash$ PSoval\{width\}\{height\} Puts a hollow ellipse with its center at the position specified by \put.
$\backslash$ PSoval*\{width\}\{height\} Puts a solid ellipse with its center at the position specified by \put.
$\backslash \operatorname{PStilt}(\Delta x, \Delta y)\{$ object $\}$ Puts object at the position specified by $\backslash p u t$, but at a slope $\Delta y / \Delta x$. object can be text, or any picture environment object such as loval, \PSarrowhead, or $\backslash$ framebox with their appropriate arguments included.
$\backslash \operatorname{PSpath}\left(x_{0}, y_{0}\right)\left\{\left(x_{1}, y_{1}\right) \cdots\left(x_{n}, y_{n}\right)\right\}$ Connects the points $\left(x_{i}, y_{i}\right)$ with straight lines starting at the point ( $x_{0}, y_{0}$ ) and ending with $\left(x_{n}, y_{n}\right)$. Can have an arbitrary number of points, but the exact number varies from system to system.
no longer documented; see page 199 of the LATEX manual. He pointed out that, our "oval" shape is actually an ellipse, while his, though not an oval, is a convenient shape in which to insert text. Textset
plans to implement several other of his suggestions into the program.

## Figure 5.

This extended LATEX code and the DVILASER/PS system produced the map in Figure 6 (facing page).

Figure 6.
